	Animals are groups of organisms that need to consume food to survive. Food provides energy and the building blocks of growth.	Things that are living, move, feed, grow, reproduce and use their senses Explore and compare the differences between things that are living, dead and things that have never been alive	All vertebrates have internal skeletons that protect vital organs. Invertebrates have exoskeletons that protect vital organs. Skeletons support the weight of land animals.	Animals need a variety of foods to help them grow and survive. The main food groups are: Meat, dairy and pulses provide protein for muscles. Grains and root vegetables provide carbohydrates for energy. Fat for insulation and energy.	All animals need oxygen to survive. Air is breathed into the lungs where the oxygen in the air is passed into the blood.	

There are many different groups of animals including fish, amphibians, reptiles, birds and mammals.

They have different structures, and they eat different types of foods.

The structure of a variety of common animals varies: Mammals have hair/fur and give birth to live young, fish can breathe underwater using gills, birds have feathers, beaks and wings. Females lay eggs. Most birds can fly, reptiles are air breathing and have scaly skin and lays eggs, and amphibians have smooth slimy skin and live on land and in water.

Some eat other animals (carnivores), and others only eat vegetables (herbivores), and some like to eat both plants and meat (omnivores)

Common animals that are carnivores include lions, cats, sharks and snakes

Common animals that are herbivores include cows, horses, sheep, elephants and deer

Common animals that are omnivores include humans, bears, monkeys and seagulls

Animals must move to get their food

They will move in different ways to get their food

Animals that eat other animals are called predators

Animals grow until they reach maturity and then don't grow any larger

Animals reproduce when they reach maturity (adulthood)

All animals eventually, die

Different animals live to different ages

Different animals reach different sizes before they are able to reproduce

Different animals reproduce at different ages

Animals, including humans, have offspring which grow into adults

Exercise, eating the right amounts of different types of food and hygiene are important to maintain good health and wellbeing

Habitats are places where animals and plants live (from Year 1)

Animals live in habitats in which they are suited.

Identify and name a variety of animals in their habitats.

Different kinds of animals and plants depend on each other within habitats.

Animals get their food from plants and other animals.

This can be shown in a food chain.

Stronger bones can support a greater mass.

Bones are connected (but can move relative to each other) at joints.

Muscles connect to bones and move them when they contract.

Stronger bones can anchor stronger muscles.

Fruit and vegetables for minerals, vitamins and fibre. These are essential to keep our bodies working well and protect us from illnesses.

Different animals require different foods to survive.

Animals get their food from plants and other animals. This can be shown in a food chain. (From Year 2)

A food chain begins with a producer. This is often a green plant because plants can make their own food. (From Year 2)

A living this that eats other plants is called a consumer. (From Year 2)

Humans require a balanced diet to remain healthy but healthy diets vary depending upon the type of activity that humans do.

Humans have 2 sets of teeth in their lifetimes

Humans have three main types of teeth-incisors, canines and molars.

Incisors help to bite off and chew pieces of food.

Canines are used for tearing and ripping food.

Molars help to crush and grind food.

Every part of animals' bodies need oxygen, especially muscles.

Muscles need a supply of oxygen and sugar (glucose) to make them work, they are supplied by the blood.

The heart is a vital organ pumps blood through the blood vessels.

Blood Vessels are the tubes that blood flows through.

The blood circulates around the body in a way that ensures all muscles in the body get a supply of oxygen and sugar.

The heart pumps blood to every muscle in the body. The circulatory route must allow the blood to collect oxygen from the lungs, sugar from the intestines and visit muscles.

The blood then returns to the heart where it is pumped again.

Exercise helps the heart to work more efficiently.

Eating a healthy diet helps to keep the blood vessels from getting blocked.

Avoiding smoking and alcohol puts less stress on the whole system and keeps it healthier.

	Animals that are eaten by other animals are called prey Animals feeding relationships can be illustrated in a food chain Identify, name, draw and label the basic parts of the human body and say which part of the body is associated with each sense. The five sense organs are the eyes (for seeing), nose (for smelling), ears (for hearing), tongue (for tasting), and skin (for touching or feeling). Animals have senses to help them survive Animals have developed a range of ways to find prey or avoid being eaten Animals have developed a range of ways to find prey or avoid being eaten	A food chain begins with a producer. This is often a green plant because plants can make their own food. A living thing that eats other plants is called a consumer.	The nutrients in food have to get to every part of the body. The blood transports them. The role of digestion is to get the nutrients in food to dissolve in the blood, if it doesn't dissolve it can't enter the blood and be transported.	Describe the changes as humans develop to old age. (Teach in RHE)

Plants have specific adaptations for survival To survive they need to get water, light, and avoid being eaten	Mammals, amphibians, insects and birds have different life cycles. Lifecycles vary in time depending on the species of animal- it can be as short as just a few weeks for	They show when new organisms appear and when they go extinct. Due to the nature of fossil formation and discovery,	have inherited those same successful features. Those that are not well adapted will eventually go extinct.

SEASONS Cycle A- Autumn 1 Cycle B- Autumn 1

spring
summer
autumn
winter
hibernating
migration
evergreen
deciduous

There are four seasons, Spring, summer, autumn and winter

Each season is about three months long

In Spring, young animals like lambs and chicks are born, the flowers bloom and the weather starts to become warmer.

In Autumn, the leaves fall off the trees and the amount of time we have in the day becomes less.

Winter has the shortest amount of time during the day and the weather is at its coldest.

In Summer the trees are full of green leaves and the weather is at its warmest.

(THIS SUBSTANTIVE KNOWLEDGE ALSO APPEARS IN THE PROGRESSION WITHIN THE PHYSICS- EARTH AND SPACE) insects, to up to 200 years for sea urchins.

Larger animals often have longer life cycles but not always.

All animal life cycles begin with growth and development followed by reproduction.

Some animals undergo a complete metamorphosis as they grow.

Metamorphosis is a process where animals undergo an abrupt and obvious change in the structure of their body and their behaviour.

Some animals are eusocial. This means they live in colonies (groups) with one animal or group producing young and the others working to care for them.

Environmental change affects different habitats differently

Human activity significantly affects the environment

Different organisms are affected differently by environmental change

fossils only provide an incomplete record of evolution.

Scientists use fossils along with other pieces of evidence (DNA, Embryology, comparative anatomy, artificial selection) to work out how organisms have evolved

Fossils form when dead organisms are rapidly buried or leave an imprint and are turned to stone over a long period of time. If they survive in the Earth, they then have to be found by a palaeontologist who will study them.

All living (and extinct) organisms are classified into groups based upon their physical features.

This includes animals, plants, fungi, and microorganisms like bacteria.

Within each of these broad groups, organisms are classified into small subgroups. Animalsinvertebrates, mammals, birds, amphibians, reptiles and fish, Plants-flowering plants, ferns, conifers, moss.

Bacteria are a group of organisms that are not visible to the naked eye but are very

Over a long enough timeline all organisms in a population will have those successful features.

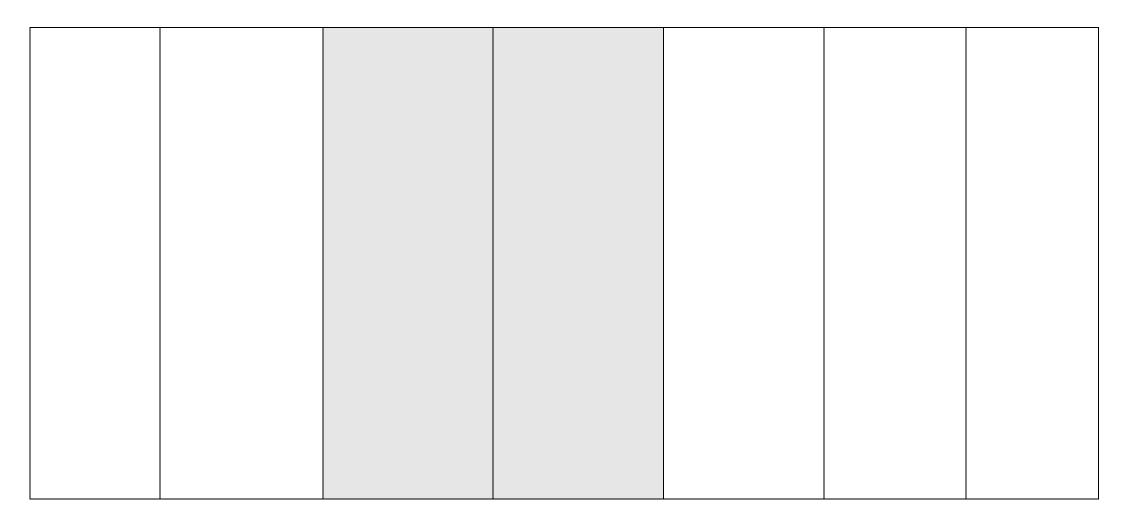

This is known as the Theory of Evolution by Natural Selection and was developed by Charles Darwin in 1859

Before Darwin, Lamarck's Idea of acquired characteristics was proposed. (Giraffes stretch their necks in life, which made their children have longer necks).

Darwin as a young man travelled around the world on the HMS Beagle. On this 5-year voyage he saw lots of things and recorded down lots of evidence which allowed him to work out how organisms change over time by a different mechanism of Natural selection

MATERIALS	DESCRIBING MATERIALS Cycle A- Autumn 2 Cycle B- Spring 1	CHANGING MATERIALS Cycle A- Autumn 2 & Spring 1 Cycle B- Autumn 2 & Spring 1	SOLIDS, LIQUIDS AND GASES Cycle A- Summer 1/2	MIXTURES AND SEPARATING THEM Cycle B- Spring 1/Spring 2	MAKING NEW SUBSTANCES Cycle B- Spring 2/Summer 1	
	Properties Metal Rock Fabric Wood Plastic Ceramic Suitable Purpose	changed physical force absorb crumbly property drag suitable strongest flexible	State Solid Liquid Gas Gravity Viscous Heating Cooling Melting Boiling Evaporate Freeze	Substance Mixture Dissolving Solution	Matter Mass React Irreversible	
	There are many different materials that have different observable properties Materials that have similar properties are grouped into metals, rocks, fabrics, wood, plastic and ceramics (including glass).	Materials can be changed by physical force (twisting, bending, squashing and stretching). The properties of a material determine whether they are suitable for a purpose.	Condense Materials can be divided into solids, liquids and gases. Solids hold their shape unless forced to change. Liquids flow easily but stay in their container because of gravity. The more viscous a liquid the less runny it is. Gases move everywhere and are not held in containers by gravity. Heating causes solids to melt into liquids and liquids to evaporate to	A substance is an object with the same properties throughout. A mixture is when more than one substance is present in the same container When a substance is added to a liquid the substance can disappear- this is called dissolving A mixture of a substance that has dissolved in a liquid is called a solution Not every substance can dissolve in uniters	Compare and group together everyday materials on the basis of their properties, including their hardness, solubility, transparency, conductivity (electrical and thermal) and response to magnets. Give reasons, based on evidence from comparative and fair tests, for the particular uses of everyday materials including metals, wood and plastic.	
			, ,		е	wood and plastic.

Different substances change state at different temperatures but the temperatures at which given substances changes state is always the same.

The temperature at which a substance melts from a solid to a liquid is the same at which it freezes from a liquid to a solid.

The temperature at which a substance boils from a liquid to a gas is the same at which it condenses from a gas to a liquid.

Liquids evaporate slowly, even below their boiling temperatures.

The water cycle is the process by which water is continuously transferred between the surface of the earth and the atmosphere.

Liquid water evaporates into water vapor, condenses to form clouds, and precipitates back to earth in the form of rain and snow.

ROCKS AND SOILS Cycle A- Autumn 1

Rock (from 'Describing Materials' yr 1) Crystal

> Mineral Ore Grains

Fossil

Sedimentary Igneous Mixtures can be separated if the substances have different properties

This is because the substances in the mixture are still present and are unchanged

There are different techniques for separating mixtures

- Filtration requires the substances be one that does not dissolve in a liquid to work.
- Sieving requires the substances to be of different sizes to work
- Magnets requires the substances to be some magnetic materials and some non-magnet materials to work.
- Evaporation requires a solid substance dissolved in water and the solid has a higher boiling point in water to work.
- Floating requires some substances to float and some substances to sink to work.

Sometimes, mixed substances react to make a new substance.

These changes are usually irreversible.

Heating can sometimes cause materials to change permanently.

When this happens, a new substance is made. These changes are not reversible.

Indicators that something new has been made are the properties of the material are different (colour, state, texture, hardness, smell, temperature)

If it is not possible to get the material back easily it is likely that it is not there anymore and something new has been made (irreversible change)

Metamorphic
Porosity
Hardness
Soil
Humus
Silt
Jiit I I I I I I I I I I I I I I I I I I
A rock is a solid material made up of
minerals forming part of the surface
of the Earth
Rocks are exposed on the surface at
cliffs, hills and mountains but are
also under the surface.
Samurada all'idano carrie
Some rocks, called ores contain metals
lifectals
Some rocks are made of grains
squashed together and can contain
the remains of long-dead organisms,
called fossils. This type of rock is
called sedimentary rock, an example
would be limestone, sandstone or
mudstone
Some rocks are made of crystals that
are locked tightly together. These
are called igneous and metamorphic rocks; an example of igneous rock is
granite, and an example of
metamorphic rock is slate
These three types of rocks all have
different properties to each other,
including porosity, hardness,
reaction to chemicals
The properties of the rock depend
on how the rock was formed, e.g.
Some igneous rocks form from lava from volcanoes and cool very
quickly leading to very small crystals
quickly icading to very small crystals

		Soil is made up of small broken- down pieces of rock. Soil contains a range of different size rock pieces, e.g., sand grains or stones. Soil also contains humus (rotted plant material) Soil made of very fine rock is called silt or clay.

	become warmer.		Our solar system consists of 8 planets, many of those planets have moons which orbit around them.	

In autumn, the leaves fall off the trees and the amount of time we have in the day becomes less.

Winter has the shortest amount of time during the day and the weather is at its coldest.

In summer the trees are full of green leaves and the weather is at its warmest.

Animals and plants have adapted ways of surviving the changing seasons

These include hibernating, storing food, fattening up, migration, loss of leaves

Trees can be either evergreen or deciduous.

Evergreen trees keep their green leaves all year round.

Deciduous trees lose their leaves every autumn.

(THIS SUBSTANTIVE KNOWLEDGE ALSO APPEARS IN THE PROGRESSION WITHIN THE BIOLOGY- VARIATION AND EVOLUTION) Earth's moon is not a planet but is a satellite which orbits Earth. It is around a quarter of the size of Earth.

As the Moon orbits the Earth, the Sun lights up different parts of it, making it seem as if the Moon is changing shape. We call these the phases of the moon.

The Moon doesn't emit (give off) light itself, the 'moonlight' we see is actually the Sun's light reflected off the lunar surface.

Our solar system can be represented with a model but it isn't possible to draw it to scale.

The planets and moons are rotating (spinning)

The time it takes one planet to rotate is called a day. On Earth this is 24 hours

The time it takes a planet to complete one orbit around its star is called a year. On Earth this is 356.25 days

The solar system is with a massive collection of stars called the galaxy (called the Milky way)

The Milky way is one of billions of galaxies in the Universe.

		Stars are huge balls of gas that produce vast amounts of light and heat. Asteroids are lumps of rock that orbit a star (there are millions in between Mars and Jupiter) Comets are objects that are made of Ice, which melts when they get closer to the sun leaving a tail. Gravity is force of attraction between two objects with mass (a quantity of matter) The bigger the mass the bigger force it exerts Gravity works over distance but gets weaker as distance increases Stars, planets, moons have a very large amount of mass. They exert a gravitational attraction on each other Differences in gravity result in smaller mass objects orbiting around lager mass objects, e.g., planets around stars and moons around planets
